

## Encoding v. Hashing Assignment

### Step 1

Type in 'echo You guys are AWESOME! | base64' in the Linux interface

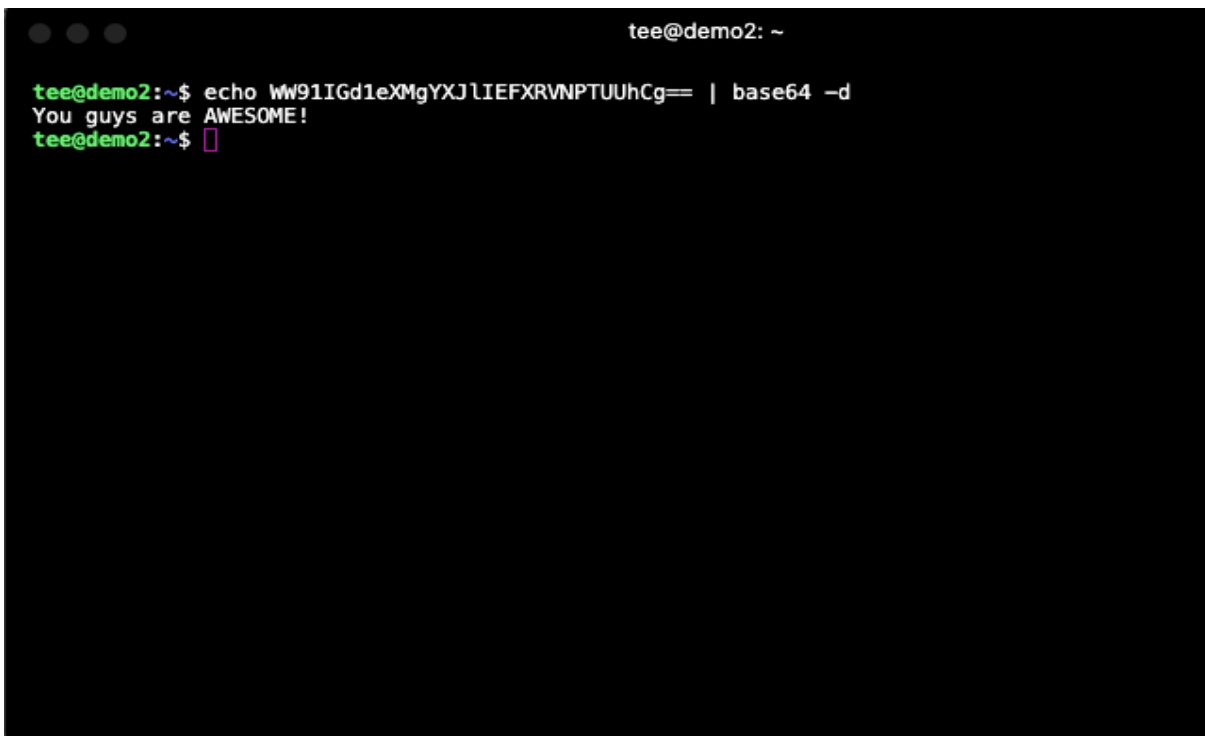

A terminal window titled 'tee@demo2: ~' with a dark background. The prompt is 'tee@demo2:~\$'. The user enters the command 'echo You guys are AWESOME! | base64'. The output is 'Ww91IGd1eXMgYXJlIEFXRVNPTUUhCg=='. The prompt changes to 'tee@demo2:~\$' with a green cursor.

```
tee@demo2: ~  
tee@demo2:~$ echo You guys are AWESOME! | base64  
Ww91IGd1eXMgYXJlIEFXRVNPTUUhCg==  
tee@demo2:~$
```

This command encodes the text "You guys are AWESOME" using base64 as displayed above. The output of the coded text can also be seen above.

### Step 2

Type in 'echo <encoded output> | base64 -d' to decode the previously encoded text line. This is illustrated below:

A terminal window titled 'tee@demo2: ~' with a dark background. The prompt is 'tee@demo2:~\$'. The user enters the command 'echo Ww91IGd1eXMgYXJlIEFXRVNPTUUhCg== | base64 -d'. The output is 'You guys are AWESOME!'. The prompt changes to 'tee@demo2:~\$' with a green cursor.

```
tee@demo2: ~  
tee@demo2:~$ echo Ww91IGd1eXMgYXJlIEFXRVNPTUUhCg== | base64 -d  
You guys are AWESOME!  
tee@demo2:~$
```

This shows that an encoded text can be decoded to reveal the plaintext format.

### Step 3

Type 'echo This is evil naughty naughty malware > malware.txt'

```
tee@demo2: ~  
  
tee@demo2:~$ ls  
blue          ebil.txt      file2.txt     Linux64.zip   notmalwarereally.txt  test2.txt  
catpictureess.jpg file1.txt     file3.txt     mobydick.txt  pg2701.txt            vt  
tee@demo2:~$ echo This is evil naughty naughty malware > malware.txt  
tee@demo2:~$ ls  
blue          ebil.txt      file2.txt     Linux64.zip   mobydick.txt          pg2701.txt  vt  
catpictureess.jpg file1.txt     file3.txt     malware.txt   notmalwarereally.txt  test2.txt  
tee@demo2:~$
```

The above command creates and writes the text "This is evil naughty naughty malware" to a file named malware.txt file. To confirm this, cat the malware.txt file as illustrated below:

```
tee@demo2: ~  
  
tee@demo2:~$ cat malware.txt  
This is evil naughty naughty malware  
tee@demo2:~$
```

To encode the content of the file malware.txt and save them in a new file, use the following command: `cat malware.txt | base64 > notmalwarenotreally.txt`. This is illustrated below:

```
tee@demo2: ~  
tee@demo2:~$ cat malware.txt | base64 > notmalwarenotreally.txt  
tee@demo2:~$ cat notmalwarenotreally.txt  
VGhpcyBpcyBldmlsIG5hdWdodHkgbmF1Z2h0eSBtYWx3YXJlCg==  
tee@demo2:~$
```

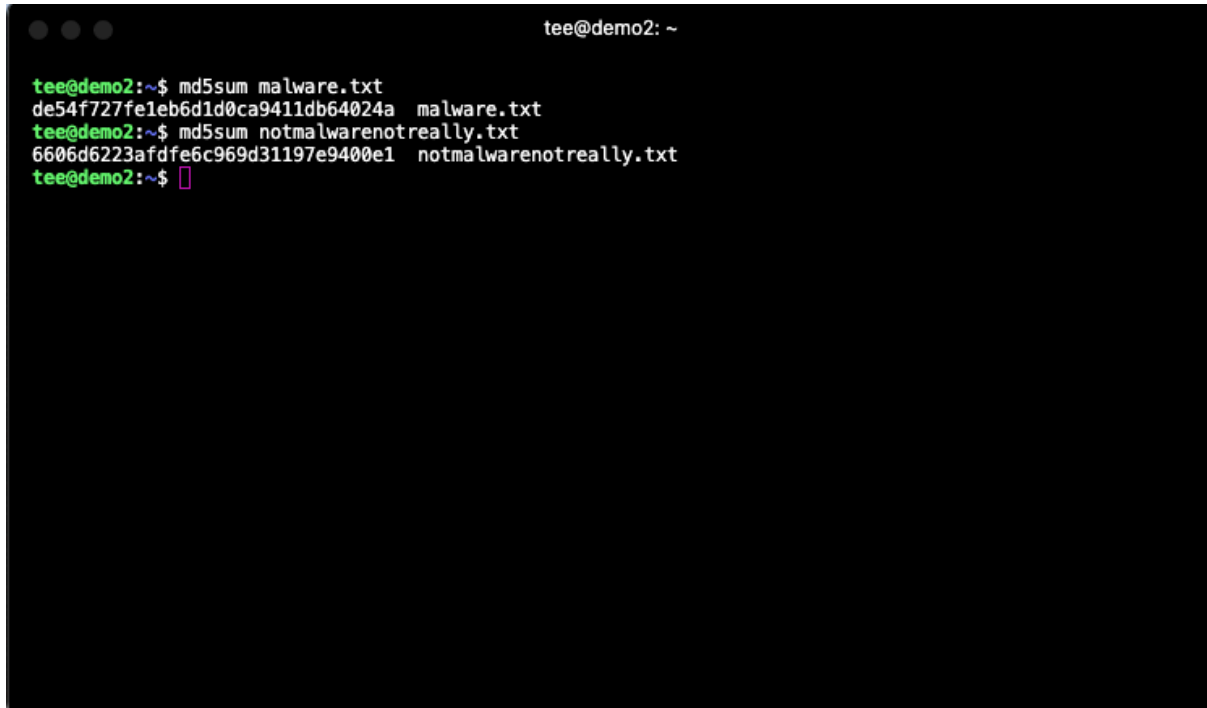

As shown above, catting the new file notmalwarenotreally.txt reveals the coded content of the file. It is encoded and NOT human readable. To decode the content of this file, the following command will be used: `cat notmalwarenotreally.txt | base64 -d` as illustrated below:

```
tee@demo2: ~  
tee@demo2:~$ cat notmalwarenotreally.txt | base64 -d  
This is evil naughty naughty malware  
tee@demo2:~$
```

This confirms that the encoding and decoding was successful.

#### Step 4

Finally, both files (malware.txt and notmalwarenotreally.txt) will be hashed to establish that even though they carry the same content, the plaintext version will carry a different hash compared to the encoded version. To achieve this, both files will be hashed using the 'md5sum' command as shown below:

A terminal window with a black background and green text. The title bar at the top right says 'tee@demo2: ~'. The terminal shows the following commands and outputs:

```
tee@demo2:~$ md5sum malware.txt
de54f727fe1eb6d1d0ca9411db64024a  malware.txt
tee@demo2:~$ md5sum notmalwarenotreally.txt
6606d6223afdf6c969d31197e9400e1  notmalwarenotreally.txt
tee@demo2:~$
```

This is an example of how attackers can use encoding to disguise malicious files in order to bypass signature based antivirus systems.
